H Ch 11

**FIND EQUIVALENCE POINT FIRST**

**CORRECT MOLARITY AS TITRANT IS ADDED**

**H 11-4 Polyprotic Titrations**

homework for week 14,15  
due dates this Wednesday  
and Friday

# Titration

---

## Titration of a Strong Base with a Strong Acid

EX: 50.00 mL of 0.02000 M KOH titrated with 0.1000 M HBr.

**chemical equation** (why reaction arrow?)

**net ionic equation**

## Titration of a Weak Acid with a Strong Base

EX: 50.00 mL of 0.02000 M MES,  $pK_a = 6.27$ , titrated with 0.1000 M NaOH.

**chemical equation** (why reaction arrow?)

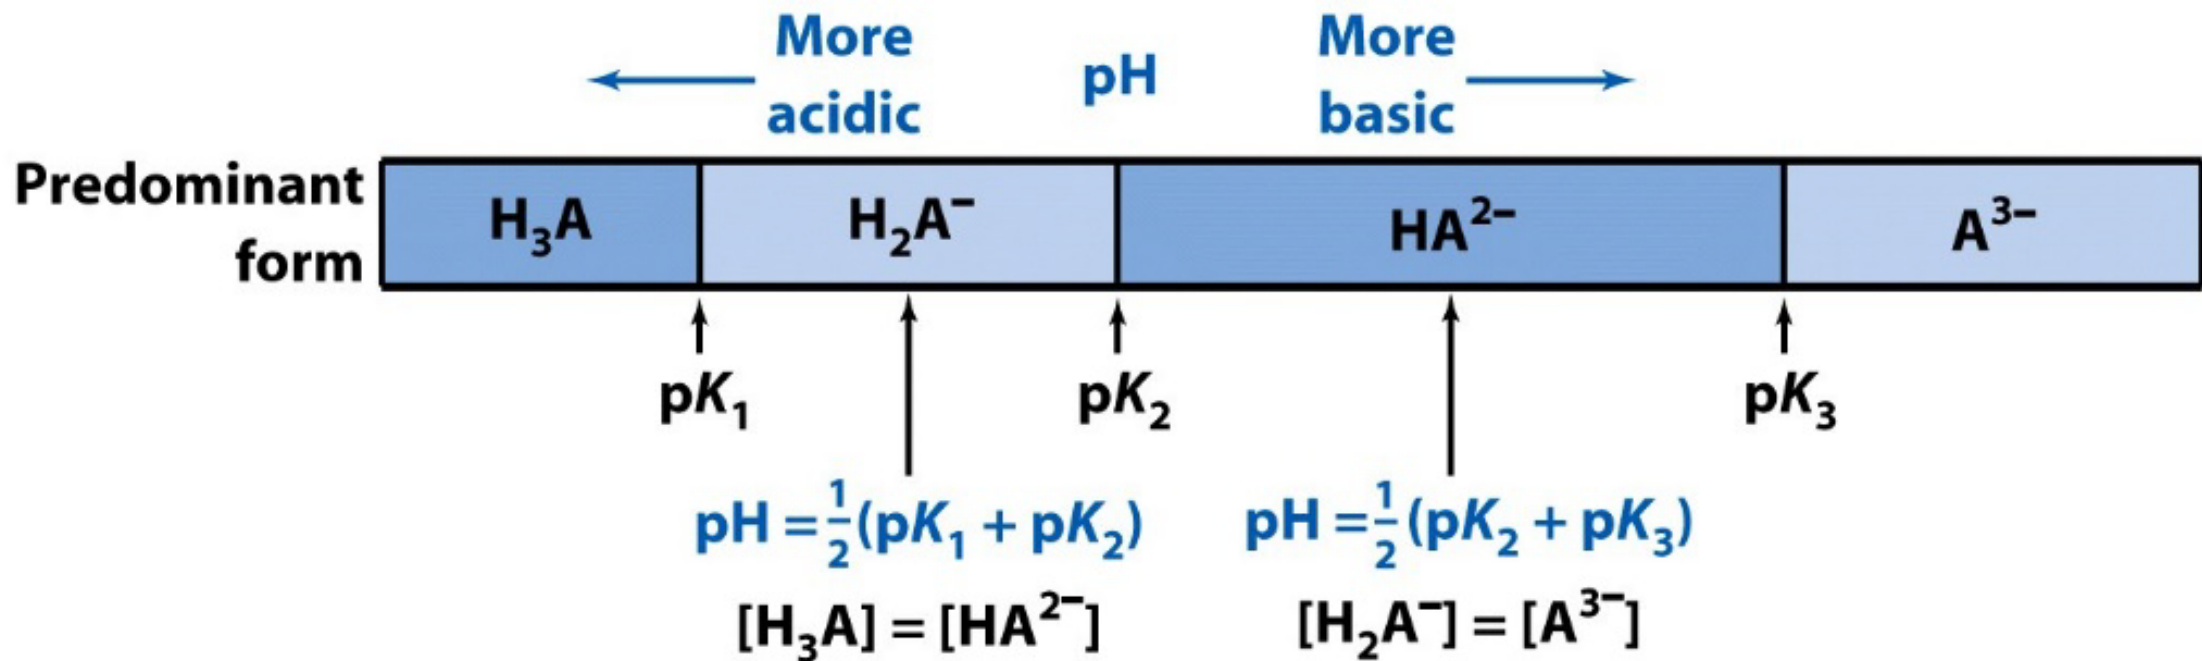

**net ionic equation**

# Finding the Principal Species at a Given pH

$$\text{pH} = \text{p}K_a + \log [\text{base}] / [\text{acid}]$$

# Finding the Fraction Dissociated at a Given pH

$$pH = pK_a + \log \frac{[base]}{[acid]}$$

Strongest acid (base) that can exist in a solvent is the **acidic** (**basic**) autoionization species of the solvent.

# Blackbody Radiation and the Greenhouse Effect

Balance between energy reaching Earth from the sun and energy reradiated to space.

# Greenhouse Effect

Average temperature of earth's surface is about **59°F**. Without any greenhouse gases it would be near **-2°F**.

**greenhouse gases:**  
carbon dioxide,  $\text{CO}_2$   
methane,  $\text{CH}_4$   
(30 times more potent than  $\text{CO}_2$ )  
Nitrous oxide,  $\text{N}_2\text{O}$

**FIGURE 0-5** *Greenhouse effect.* The sun warms the Earth mainly with visible radiation. Earth emits infrared radiation, which would all go into space in the absence of the atmosphere. Greenhouse gases in the atmosphere absorb some of the infrared radiation and emit some of that radiation back to the Earth. Radiation directed back to Earth by greenhouse gases keeps the Earth warmer than it would be in the absence of greenhouse gases.

Harris, *Quantitative Chemical Analysis*, 8e

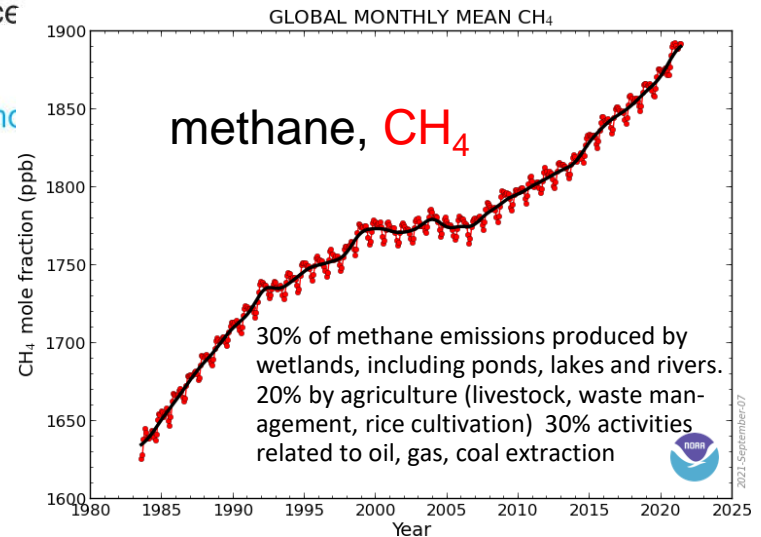

# Greenhouse Effect

Average temperature of earth's surface is about **59°F**. Without any greenhouse gases it would be near **-2°F**.

**greenhouse gases:**  
carbon dioxide, **CO<sub>2</sub>**  
methane, **CH<sub>4</sub>**

last time the atmospheric  $\text{CO}_2$  amounts were this high was more than 3 million years ago, when temperature was  $2^\circ\text{--}3^\circ\text{C}$  ( $3.6^\circ\text{--}5.4^\circ\text{F}$ ) higher than during the pre-industrial era, and sea level was 15–25 meters (50–80 feet) higher than today

# Increase in CO<sub>2</sub> Over Past 60 Years

**FIGURE 0-4** Monthly average atmospheric CO<sub>2</sub> measured on Mauna Loa. This graph, known as the *Keeling curve*, shows seasonal oscillations superimposed on rising CO<sub>2</sub>.  
[Data from [http://scrippsco2.ucsd.edu/data/in\\_situ\\_co2/monthly\\_mlo.csv](http://scrippsco2.ucsd.edu/data/in_situ_co2/monthly_mlo.csv).]

Historic CO<sub>2</sub> high of 280 ppm over 800,000 years increased to current 416 ppm in past 200 years due to burning fossil fuel (oil, coal, wood, natural gas) and destruction - “clearing” - of earth’s forests.

# Increase in CO<sub>2</sub> Over Past 60 Years

The atmospheric burden of CO<sub>2</sub> is now comparable to where it was during the Pliocene Climatic Optimum, between 4.1 and 4.5 million years ago, when CO<sub>2</sub> was close to, or above 400 ppm. During that time, sea level was about 78 feet higher than today, the average temperature was 7 degrees Fahrenheit higher than in pre-industrial times.

In February, the United States officially rejoined the Paris Agreement on climate change. Yet, as the measurements from Mauna Loa show, despite decades of negotiation, the global community has been unable to meaningfully slow, let alone reverse, annual increases in atmospheric CO<sub>2</sub> levels.

Nature withdrawing CO<sub>2</sub> from air for plant growth during summer and returning it each succeeding winter

**FIGURE 0-3** Atmospheric CO<sub>2</sub> measurements from Mauna Loa in 1958–1959. [J. D. Pales and C. D. Keeling, "The Concentration of Atmospheric Carbon Dioxide in Hawaii," *J. Geophys. Res.* **1965**, 70, 6053.]

# Pteropod

Low carbonate concentration promotes dissolution of  $\text{CaCO}_3$  shells and skeletons

Increasing atmospheric  $\text{CO}_2$  increases concentration of  $\text{CO}_2$  dissolved in oceans, which consumes carbonate and lowers the pH

**pre-industrial pH of oceans = 8.16**

**currently ocean pH = 8.04**

**without change, pH by 2100 = 7.7-7.8**

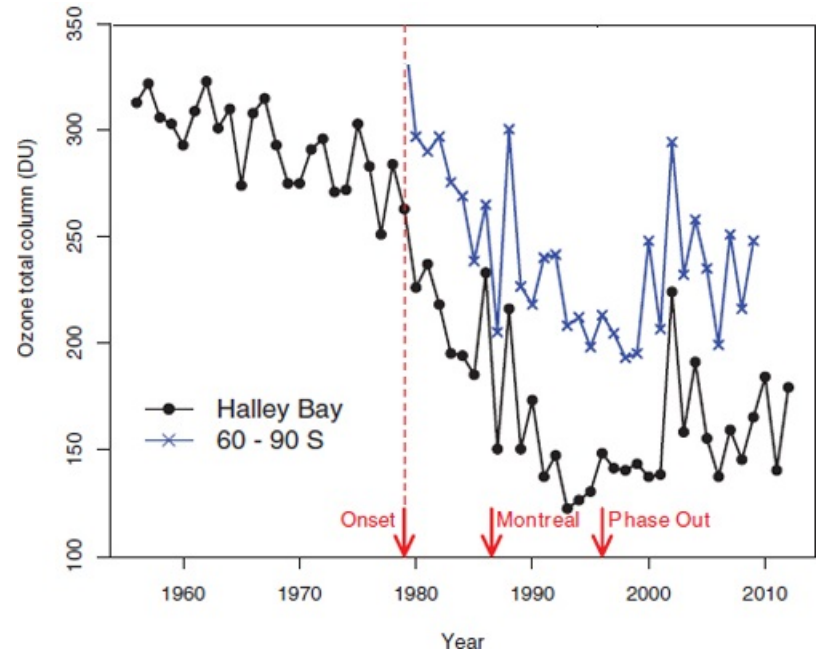

(earth not experienced such low pH in > 20 million years)

**shell beginning to dissolve**

# The Ozone Hole

A success story – use of Freons stopped (**Montreal Protocol**) and hole is healing  
bans emissions of ozone depleting chemicals

Big hole (size of North America) still there but ozone concentration does not appear to be decreasing further.

(estimates than hole will "heal" –  
attain pre-1980 levels – by 2060)
