Water droplets shape graphene nanostructure

Posted In: Environment

By EurekaAlert

Thursday, December 17, 2009

Graphene - A single-atom-thick sheet of carbon, like those seen in pencil marks - offers great potential for new types of nanoscale devices. If a good way can be found to mold the material into desired shapes.

Chemists at the University of Illinois at Chicago say it's possible, reporting that graphene can become quite pliable using only a nanodroplet of water to do the job.

"Up until now, it wasn't thought we could controllably fold these structures," said Peter Kral, assistant professor of chemistry at UIC. "But now we know how to shape graphene by using weak forces between nanodroplets carefully positioned on graphene sheets."

Kral and two of his graduate students described the process in a recent article in *Nano Letters*, which is highlighted in *Nature's* "news and views" section Dec. 17.

Engineers already cut graphene into narrow ribbons and other shapes, expanding the set of carbonaceous systems such as fullerenes, carbon nanotubes and nano-diamonds. Using computer simulations, Kral showed that weak molecular interactions called van der Waals forces between water nanodroplets and graphene can shape it into a wide variety of forms, without the water and graphene chemically binding.

"Depending on the size of the water droplet and the shape and size of graphene flake used, we can fold it in different shapes for various applications," said Kral. "It's similar to the way proteins are folded in biological cells with the help of chaperone proteins."

Kral and his students discovered they could use water droplets to roll, bend, slide and shape graphene into different complex structures such as capsules, sandwiches, knots and rings - all potential building blocks of nanodevices with unique mechanical, electrical or optical properties. By using special techniques like atomic force microscopy and carefully guided microscopic needles, water droplets and other materials can be carefully positioned on graphene to shape it into desired forms, he says.

Kral's laboratory is studying potential uses of nanoscale graphene, such as ways to coat it with phospholipid molecules that would allow it to become part of biological cell membranes where it might perform specific functions. His lab is also designing graphene sheet nanoscale pores that allow the building of novel ion and molecular separation membranes for use in desalination and other applications.

While the materials he works with are inorganic, Kral sees a growing trend to developing hybrid multifunctional systems that combine inorganic nanostructures with biological cellular systems.

"We're trying to detect signals from the biological world or pass signals to the biological world," he said. "In the future, perhaps proteins will evolve to interact with inorganic systems. It's a way of evolution to form a new interface, or hybrid system, working together on novel functions."

Multi-parameter portable meters
10 hours ago

Mettler Toledo introduced a new range of multi-parameter portable meters for measurements of pH, conductivity, dissolved oxygen, and ion concentration. All three instruments are based on the rugged design of SevenGo and are watertight according to IP67.

Dimensional measurement and inspection technology
10 hours ago

The new IM-6000 Series is a step forward in the field of high precision dimension inspection. Innovative Pattern Registration and Pattern Search functions provide simplified "Place and Press" measurement operation.
